Problem Description

Options Considered

ZeroMQ

Need to design and create protocol, done in **SDIS**

PeerJS

WebRTC wrapper to communicate between peers

Kademlia

DHT using asyncio and python sockets

LibP2P

Variety of **Modules** implemented in Go/JS

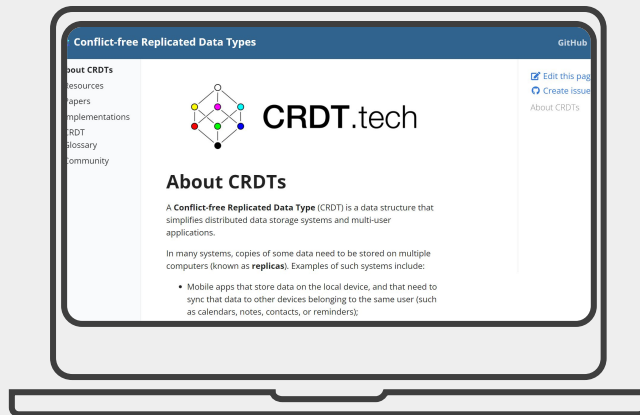

gun.

node JS

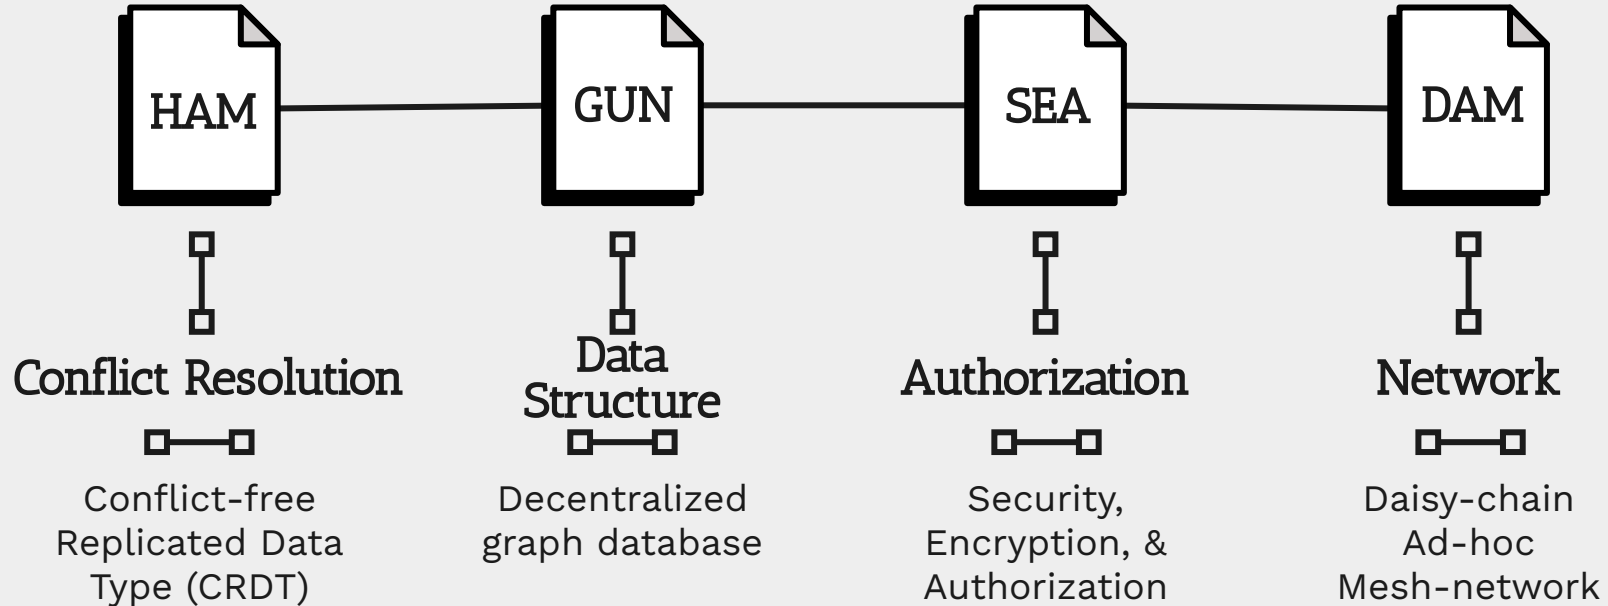

React

Conflict-free Replicated Data Types

<< For more details on CRDTs, you can read the article
“Conflict-free Replicated Data Types” by Nuno Preguiça,
Carlos Baquero, and Marc Shapiro (2018) >>

Gun Ecosystem

CAP Theorem

Consistency

Gun opts for eventual consistency instead of strong consistency

Availability

All requests retrieve a **non-error** response

Partition Tolerance

Peers can be **offline** and still operate over their data

Gun Network

Peer

Keep localized graph in local Storage

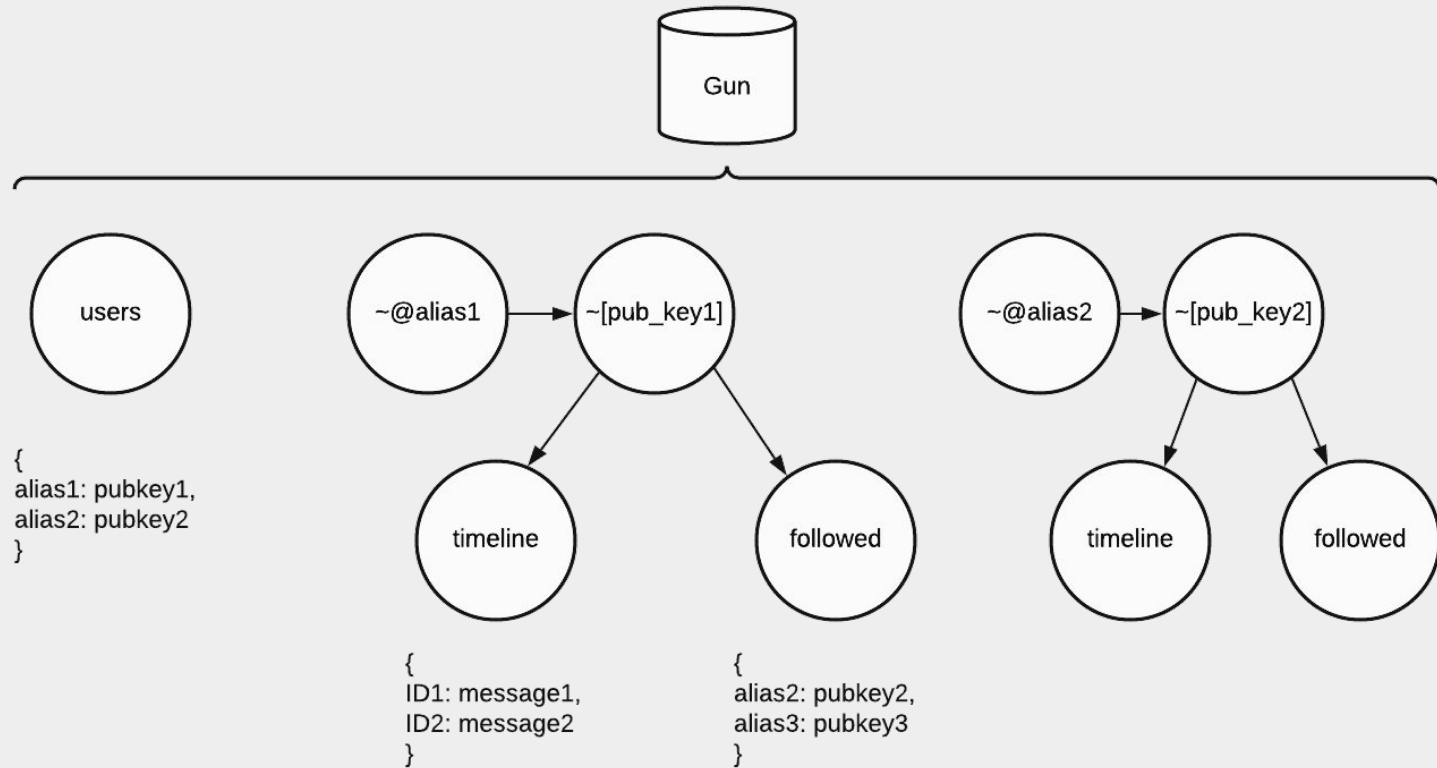

Relay Server

Persistent storage, serves as bootstrap

Graph Structure

Authentication - SEA

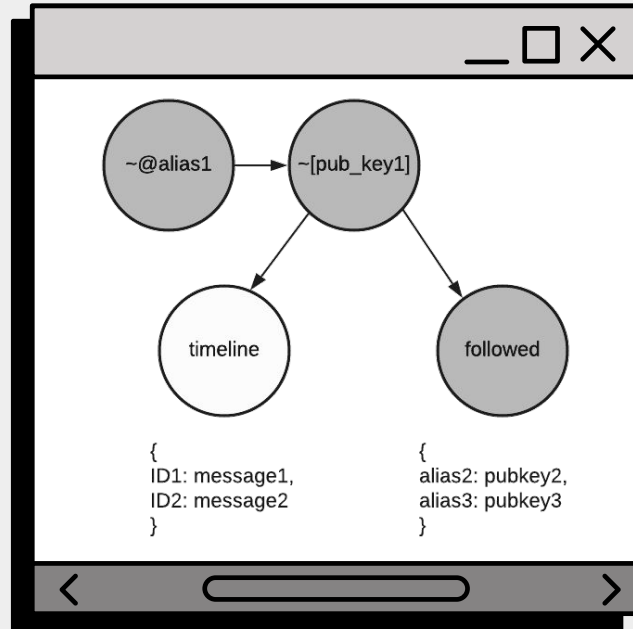

A user can create an account with an **alias** and a **password**.

If the alias is not taken, the user is created and authenticated. A **private** and **public** key pair is created and the user publishes his alias and pub key to the users node.

The user information is stored in the browser's session storage.

Timeline

Post a message

A new node is added to the timeline with its content and ID as `Date.now()`

Delete a message

Reference to the node becomes null, possible to restore message

Followed

Following a user

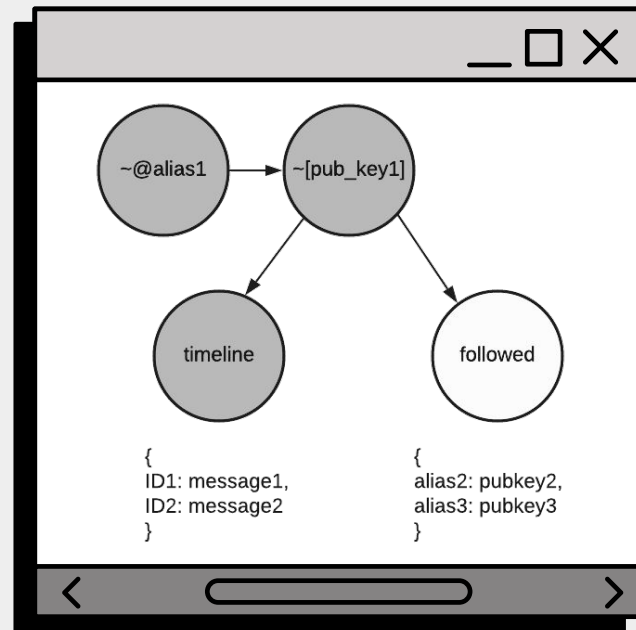

A subscription to that user's timeline node is performed

Followed node

Contains nodes with followed user's information

Ephemeral Messages

The browser's local
storage and Gun's
management combined

Realtime Updates

Due to GUN's use of **PTSD** (Performance Testing Speed Development), a strong focus on benchmarking ops/s makes real time updates possible

Thanks!
